

one pass, and then scans the even lines on the second pass. This results in an almost unperceivable sticker that can cause eye strains.

VIDEO TECHNOLOGIES: Video technologies differ in many different ways. However, the major two differences are resolution and the number of colors it can produce at those resolutions.

- **RESOLUTION:** This is the number of pixels that are used to draw an image on the screen. It is given as two numbers, one being the number of pixel across the screen and the other, the number of pixels down the screen. If there were 800 pixels across and 600 pixels down the side, then the resolution would be 800 x 600. Multiply 800 times 600 and you will get the number of pixels used to draw the image (480, 000 pixels in this example).
- **MONOCHROME:** Monochrome monitors are very basic displays that produce only one color. The basic text mode in DOS is 80 characters across.
- **CGA/EGA:** The color graphics adapter (CGA) introduced color to the personal computer. It can produce a resolution of 320 x 200 and has a palette of the colors but can only display 4 at a time. The Enhanced Graphics Adapter (EGA) was capable of a resolution of 640 x 350 pixels and could display 16 colors from a palette of 64.
- **VGA:** The video Graphics Array (VGA) adapter was capable of a resolution of 640 x 480 pixels and could display up to 256 colors from a palette of over 260,000. This technology has become the standard for almost every video card and monitors being development.
- **SVGA:** Super VGA is based on VGA standards and describes display system with several difference resolutions and a varied number of colors.
- **XGA:** Extended Graphics Array (XGA) improves on the VGA standard. It had its own coprocessor and bus mastering ability.
